

What this audit can — and cannot — establish

Interface physics

Rigid no-slip sphere $\neq$ clean bubble $\neq$ validated lipid-shell SonoVue model

Confinement

A small particle Reynolds number does not establish an unbounded-flow regime.

Three-dimensional flow

A local strain-rate scalar and a candidate direction do not validate simple-shear theory.

Evidence boundaries

Saved-state timing, incomplete paths, zero-slip limits and missing outlet routes remain explicit.

The new 2.0 mm/s field has no matched MB trajectories: slip-dependent lift is not evaluable.
